#### Abstract

In power system, minimizing the power loss in the transmission lines and/or minimizing the voltage deviation at the load buses by controlling the reactive power is referred as optimal reactive power dispatch (ORPD). This paper presents an improved evolutionary algorithm based on oppositional krill herd algorithm (OKHA) for obtaining optimal steady-state performance of power systems. This article also proposes the effect of UPFC location in steady-state analysis and to demonstrate the capabilities of UPFC in controlling active and reactive power flow within any electrical network. To verify the effectiveness of KHA and OKHA, two different single objective functions such as minimization of real power losses and improvement of voltage profile and a multi-objective function that simultaneously minimizes transmission loss and voltage deviation have been studied through standard IEEE 57-bus and 118-bus test systems and their results have been reported. The study results show that the proposed KHA and OKHA approaches are feasible and efficient.

## Introduction

Transmission network is the most important component in competitive electricity markets and serves as the key mechanism for generators to compete in the supply to reach large users and distribution companies. In competitive electricity markets [1], energy prices and transmission pricing are highly affected by transmission congestion and other system constraints, where a congested transmission is accompanied by higher costs due to resorting to out-of-merit order as expensive generating units are dispatched to alleviate congestion [2]. Therefore, an increased attention has been paid to new devices that provide more flexibility to operate the transmission system and guarantee lower-cost mechanisms by which transmission constraints can be mitigated.

Available transfer capability (ATC) is the measure of the ability of interconnected electric power systems to reliably move or transfer power from one area to another over all the transmission lines between those areas under specified system conditions [3]. To operate the power system safely and to gain benefits of the bulk power transfer, the transfer capabilities must be calculated and the power system operated so that the power transfers do not

[^0]exceed the transfer capability. ATC is significantly limited by heavily loaded circuits or buses with relatively low voltages. Flexible AC transmission system (FACTS) technology makes it possible to redistribute line flow and regulate bus voltages. It can be used effectively for the enhancement of ATC.

Continuous and fast improvement of power electronics technology has made FACTS as a promising concept for power system applications during the last decade [4,5]. The use of FACTS controllers provides a flexible controlling of power flow along the transmission lines. It can reduce the flows of heavily loaded lines, maintain the bus voltages at desired levels, and improve the stability of the power network. The UPFC [6,7] is the most versatile FACTS controller envisaged so far. It can not only perform the functions of the STATCOM, TCSC and the phase angle regulator but also provides additional flexibility by combining some of the functions of the above controllers. The UPFC can provide simultaneous control of all basic power system parameters. It can fulfill functions of reactive shunt compensation, series compensation and phase shifting meeting multiple control objectives. From a functional perspective, the objectives are met by applying a boosting transformer injected voltage and an exciting transformer reactive current. The injected voltage is inserted by a series transformer.

In the last decade, various algorithms have been developed for the optimal power flow (OPF) incorporating with UPFC device as well as for the optimal placement of UPFC. Some of them are: a sensitivity based approach which has been developed for finding

suitable placement of UPFC [8], an evolutionary-programmingbased load flow algorithm for systems containing UPFC [9], a genetic algorithm (GA) which proposed for solving the optimal location problem of UPFC [10], particle swarm optimization (PSO) for optimal location of FACTS devices [11], etc.

Ara et al. [12] proposed a solution procedure using nonlinear programming (NLP) and mixed-integer nonlinear programming (MINLP) for solving the optimal location and setting of FACTS incorporated in the optimal power-flow problem with the objective functions being considered are the total fuel cost, power losses, and system loadability with and without FACTS installation and improving the power system operation. Sawhney and Jeyasurya [13] presented the application of UPFC to improve the transfer capability of a power system to meet some of the challenges of power system operation caused by deregulation in the electric power industry and opening of the market for delivery of cheaper
energy to the customers. Alomoush [14] developed a mathematical approach allocating the contributions of UPFCs to transmission system usage by making use of a dc-based load flow model of UPFC-inserted transmission lines based on a previously derived dc-based injection model of UPFC-embedded lines. Relationships were derived to model the impact of UPFC on line flows and transmission usage by using modified admittances and distribution factors that model impact of utilizing UPFC on line flows and system usage. Taher and Amooshahi [15] presented the application of hybrid immune algorithm (HIA) such as immune GA (IGA) and immune PSO (IPSO) to find optimal location of UPFC to achieve optimal performance of power system. Simulations were performed on IEEE 14 -bus and IEEE 30 -bus test systems considering the overall cost function as the objective function, including the total active and reactive production cost function of the generators and installation cost of UPFCs. Shaheen et al. [16] presented a new

Fig. 2. Transmission loss convergence graph using different algorithms of IEEE 57-bus without UPFC.
approach based on differential evolution (DE) technique to find out the optimal placement and parameter setting of UPFC for enhancing power system security under single line contingencies. Vural and Tümay [17] focused on the mathematical modeling of UPFC for the implementation of the device in conventional NewtonRaphson (NR) power flow algorithm and in power system analysis software package (PSASP). Visakha et al. [18] presented an approach for selecting suitable locations of UPFC considering normal and network contingencies after evaluating the degree of severity of the contingencies.. Roy et al. proposed biogeography based optimization (BBO) [19] to solve TCSC and TCPS based optimal reactive power dispatch (ORPD) problem for minimizing voltage deviation and transmission loss of IEEE 30-bus test system.

Panda [20] investigated the application of non-dominated sorting in genetic algorithms-II (NSGA-II) technique for designing a FACTS based controller to improve the stability of the power system with minimum control effort. The proposed technique was applied for generating a Pareto set of global optimal solutions to the multiobjective optimization problem. Furthermore, the best compromise solution from the obtained Pareto solution set was chosen by using a fuzzy-based membership value assignment method. Edward et al. [21] developed an enhanced bacterial foraging algorithm (EBFA) by including Nelder-Mead (NM) algorithm to conventional bacterial foraging algorithm (BFA) for better performance of power system. This was done to overcome the difficulty of optimal parameter selection of the conventional BFA technique. Hassan et al. proposed GA [22] technique for the stabilization of power systems using UPFC devices. Kumar et al. presented cat swarm optimization (CSO) approach [23] for the optimal location and sizing of UPFC in transmission system to improve the voltage profile and maximum loading parameter.

From the literature it is observed that UPFC device has hardly been used to solve optimal reactive power dispatch (ORPD) problem. This motivates the authors to incorporate UPFC to solve ORPD problems. In this study, two different objectives of ORPD namely minimization of transmission loss and minimization of voltage deviations are considered. In recent years, a new optimization technique named krill herd algorithm (KHA) inspired by herding behavior of krill individual firstly presented by Gandomi in 2012, has been successfully applied in various field of engineering. In this article, KHA algorithm is employed to find optimal location of UPFC for solving ORPD problem. Moreover, to improve the solution quality and convergence speed, opposition based learning is integrated with the conventional KHA algorithm. In order to show the effectiveness of the proposed KHA and OKHA approaches, two Standard test systems of IEEE 57-bus and IEEE 118-bus are used in this

paper. Results obtained from the proposed approaches are compared with those obtained from biogeography based optimization (BBO) and DE.

The rest of the paper is organized as follows. In section 'Problem formulation', the problem formulation is presented. In section 'Algorithms', KHA, OKHA algorithms along with BBO, DE algorithms are briefly explained. In section 'Oppositional krill herd algorithm applied to ORPD problem', OKHA developed for ORPD problems is described. In section 'Simulation results and discussion', the studies of application cases are presented and demonstrate the potential of the proposed KHA and OKHA algorithms. Finally, in section 'Conclusion', the conclusions are given.

## Problem formulation

Modeling of UPFC in power system under steady state operation
The most versatile FACTS device presently available for transmission system control is capable of providing active and reactive load flow control between its terminals. It may also provide reactive power compensation to the node to which it is connected [3,4]. UPFC can be divided into two FACTS controllers; first one is series controller and second one shunt controller. Series controller is equivalent to the SSSC and shunt controller is equivalent to STATCOM. When the STATCOM and the SSSC operate as standalone

Fig. 3. Voltage deviation convergence graph using different algorithms of IEEE 57bus with UPFC.

FACTS controllers, they exchange almost exclusively reactive power at their terminals. During the stand-alone operations, the SSSC injects a voltage in quadrature with the line current, thereby emulating an inductive and capacitive reactance at the point of compensation in series with the line, and the STATCOM injects a reactive current, thereby also emulating a reactance at the point of compensation in shunt with the line. In the steady state operation, the main objective of an UPFC is to simultaneously control the active and reactive power flow through the transmission line and bus voltage at which shunt component of the UPFC is connected. The basic schematic and power injection model of the UPFC are presented in Fig. 1. Using the power injection model of UPFC, the following formulation can be extracted
$P_{f}=P_{f h}+\sum_{j=1}^{N}\left|V_{f}\right|\left|V_{j}\right|\left|Y_{f j}\right| \cos \left(\delta_{f}-\delta_{j}-\theta_{f j}\right)$
$Q_{f}=Q_{f h}+\sum_{j=1}^{N}\left|V_{f}\right|\left|V_{j}\right|\left|Y_{f j}\right| \sin \left(\delta_{f}-\delta_{j}-\theta_{f j}\right)$
$P_{h}=P_{h f}+\sum_{j=1}^{N}\left|V_{h}\right|\left|V_{j}\right|\left|Y_{h j}\right| \cos \left(\delta_{h}-\delta_{j}-\theta_{h j}\right)$
$Q_{h}=Q_{h f}+\sum_{j=1}^{N}\left|V_{h}\right|\left|V_{j}\right|\left|Y_{h j}\right| \sin \left(\delta_{h}-\delta_{j}-\theta_{h j}\right)$
The active and the reactive power flow through the transmission line connected between the $f$ th and the $h$ th bus having UPFC may be derived as follows [24]:

$$
\begin{align*}
P_{f h}= & \left|V_{f}\right|^{2}\left(G_{p}+G_{s}\right)-\left|V_{f}\right|\left|E_{p}\right|\left|Y_{p}\right| \cos \left(\theta_{p}-\delta_{f}+\delta_{p}\right) \\
& -\left|V_{f}\right|\left|V_{h}\right|\left|Y_{s}\right| \cos \left(\theta_{s}-\delta_{f}+\delta_{h}\right) \\
& +\left|V_{f}\right|\left|E_{s}\right|\left|Y_{s}\right| \cos \left(\theta_{s}-\delta_{f}+\delta_{s}\right) \tag{5}
\end{align*}
$$

$$
\begin{align*}
Q_{f h}= & -\left|V_{f}\right|^{2}\left(B_{p}+B_{s}\right)+\left|V_{f}\right|\left|E_{p}\right|\left|Y_{p}\right| \sin \left(\theta_{p}-\delta_{f}+\delta_{p}\right) \\

\end{align*}
$$

where $V_{f}, V_{h}$ are the voltage magnitudes at the $f$ th and the $h$ th bus, respectively; $Y_{p}$ is the admittance of the parallel component; $G_{p}, B_{p}$ are the conductance and susceptance, respectively, of the parallel components; $Y_{s}$ is the summation of the admittance of the transmission line connected between the $f$ th bus and the admittance of the series component of the UPFC; $G_{s}, B_{s}$ are the conductance and susceptance, respectively, of the series components of UPFC; $\theta_{s}$ is the admittance angle of the admittance that includes the admittance of the line $\mathrm{k}-\mathrm{m}$ and the admittance of the series component of the UPFC; $\delta_{p}, \delta_{s}$ are the voltage source angle of the parallel and series components of the UPFC; $E_{p}, E_{s}$ are the voltage sources of parallel and series converters, respectively, of the UPFC devices.

## Objective functions

The main objective of ORPD problem goal is to minimize active power losses and improve the voltage profile by setting generator bus voltages, VAR compensators, and transformer taps. Therefore, the objectives of ORPD may be expressed as follows:

Table 6

## Active power loss minimization

The primary objective of ORPD is minimization of network active power loss, while satisfying the operating constraints. This objective function may be expressed as:
$f_{1}=\min \left(P_{\text {loss }}\right)=\min \left[\sum_{k=1}^{N_{\text {IL }}} G_{p}\left(V_{f}^{2}+V_{h}^{2}-2 V_{f} V_{h} \cos \theta_{f h}\right)\right]$
where $P_{\text {loss }}$ is the total active power loss; $G_{P}$ is the conductance of the $p$ th branch connected between them $f$ th and $h$ th bus; $\theta_{f h}$ is the admittance angle of the transmission line connected between them $f$ th and $h$ th bus; $N_{T L}$ is the number of transmission lines; $V_{f}$, $V_{h}$ are the voltage magnitudes of $f$ th and $h$ th bus, respectively.

## Voltage profile improvement

Minimization of deviations of voltages from desired values is required since bus voltage is one of the most important security and service quality indexes. The objective function of voltage profile improvement, i.e. voltage deviation minimization at load buses, maybe expressed as:
$f_{2}=\min \left(\sum_{f=1}^{N_{L}}\left|V_{L_{f}}-V_{L_{f}}^{s p}\right|\right)$
where $V_{L_{f}}$ is the voltage at the $f$ th load bus; $V_{L_{f}}^{S P}$ is the desired voltage at the $f$ th load bus, usually set to 1.0 p.u.

Simultaneous minimization of transmission loss and voltage deviation
In order to judge the effectiveness, the proposed method is also applied to solve multi-objective ORPD problem. In multi-objective optimization problem, a multiple objectives are optimized simultaneously while satisfying various equality and inequality constraints. In this article, to implement multi-objective OKH algorithm for minimizing both transmission loss and voltage devi-
ation simultaneously, price penalty factor approach is introduced to find the best compromising solutions. To improve the voltage profile and to reduce the transmission loss, the objective function may be described as follows:
$f_{3}=f_{1}+p f \times f_{2}$
where $f_{3}$ is the combined voltage deviation and transmission loss minimization objective function; $f_{1}, f_{2}$ are the transmission loss and voltage deviation minimization objective, and $p f$ is the price penalty factor.

## System constraints

## Equality constraint

The equality constraints of the ORPD problem are the active and reactive power balance equations. These are given by:
$P_{G_{f}}-P_{D_{f}}-V_{f} \sum_{h=1}^{N_{B}} V_{h}\left[G_{f f} \cos \left(\theta_{f}-\theta_{h}\right)+B_{f h} \sin \left(\theta_{f}-\theta_{h}\right)\right]=0$,
$f=1, \ldots, N_{B}$
$Q_{G_{f}}-Q_{D_{f}}-V_{f} \sum_{h=1}^{N_{B}} V_{h}\left[G_{f h} \sin \left(\theta_{f}-\theta_{h}\right)-B_{f h} \cos \left(\theta_{f}-\theta_{h}\right)\right]=0$,
$f=1, \ldots, N_{B}$
where $G_{f h}, B_{f h}$ are the real and imaginary part of the bus admittance matrix of the transmission line connected between them $f$ th and $h$ th bus; $P_{G_{f}}, Q_{G_{f}}$ are the active and reactive power generation of the $f$ th bus; $P_{D_{f}}, Q_{D_{f}}$ are the active and reactive load demands of the $f$ th bus.

Fig. 4. Transmission loss convergence graph using different algorithms of IEEE 118bus with UPFC.

## Inequality constraints

In ORPD problem, the inequality constraints are the restrictions on transformer tap setting, reactive power generation, bus voltage and power flow through the transmission lines.

The independent variables of ORPD problem are the generator bus voltages, transformer tap position and the amount of reactive power source installation. These inequality constraints can be given as:
$V_{G_{f}}^{\min } \leqslant V_{G_{f}} \leqslant V_{G_{f}}^{\max }, \quad f=1, \ldots, N_{G}$
$Q_{C_{f}}^{\min } \leqslant Q_{C_{f}} \leqslant Q_{C_{f}}^{\max }, \quad f=1, \ldots, N_{C}$
$T_{f}^{\min } \leqslant T_{f} \leqslant T_{f}^{\max }, \quad f=1, \ldots, N_{T}$
where $V_{G_{f}}^{\min }, V_{G_{f}}^{\max }$ are the minimum and maximum generator voltage of the $f$ th bus respectively; $Q_{C_{f}}^{\min }, Q_{C_{f}}^{\max }$ are the minimum and maximum reactive power injection of the $f$ th shunt compensator, respectively; $T_{f}^{\min }, T_{f}^{\max }$ are the minimum and maximum tap setting of the $f$ th transmission line; $N_{G}$ is the number of generators; $N_{C}$ is the number of shunt compensators and $N_{T}$ is the number of tap changing transformers.

The dependent variables of ORPD problem are the reactive power output of the generators, transmission line loading and load voltages. These constraints can be expressed as:
$V_{L_{f}}^{\min } \leqslant V_{L_{f}} \leqslant V_{L_{f}}^{\max }, \quad f=1, \ldots, N_{L}$
$Q_{G_{f}}^{\min } \leqslant Q_{G_{f}} \leqslant Q_{G_{f}}^{\max }, \quad f=1, \ldots, N_{G}$
$S_{L_{f}} \leqslant S_{L_{f}}^{\max }, \quad f=1, \ldots, N_{T L}$
where $V_{L_{f}}^{\min }, V_{L_{f}}^{\max }$ are the minimum and maximum voltage of the $f$ th load bus respectively; $Q_{G_{f}}^{\min }, Q_{G_{f}}^{\max }$ are the minimum and maximum reactive power generation of the $f$ th generator bus respectively; $S_{L_{f}}^{\max }$ is the maximum apparent power flow in the $f$ th line; $N_{L}$ is the number of load buses.

## Algorithms

## Krill herd algorithm

Krill herd algorithm (KHA) [25,26] is a novel meta-heuristic swarm intelligence optimization method for solving optimization problems, which is based on the simulation of the herding of the krill swarms in response to specific biological and environmental processes. The time-dependent position of an individual krill in 2D surface is governed by the following three main actions:
I. Movement induced by other krill individuals.
II. Foraging action.
III. Random diffusion.

These actions are briefly explain and mathematically expressed as follows:

## Motion induced by other krill individuals

The direction of motion induced, $\alpha_{i}$ is approximately estimated by the target swarm density (target effect), a local swarm density (local effect), and a repulsive swarm density (repulsive effect). For a krill individual, this movement can be defined as follows:
$M_{i}^{k}=\alpha_{i} M_{i}^{\max }+\omega_{n} M_{i}^{k-1}$
(20)
where
$\alpha_{i}=\alpha_{i}^{\text {new }}+\alpha_{i}^{\text {target }}$
$\alpha_{i}^{\text {new }}=\sum_{j=1}^{s} \Gamma_{i, j} \Psi_{i, j}$
where
$\Psi_{i, j}=\frac{x_{i}-x_{j}}{\left|x_{i}-x_{j}\right|+\operatorname{rand}(0,1)}$
$\Gamma_{i, j}=\frac{F_{i}-F_{j}}{F_{w}-F_{b}}$
$\alpha_{i}^{\text {terget }}=2\left(\operatorname{rand}(0,1)+\frac{i}{i_{\max }}\right) \Gamma_{i}^{\text {best }} \Psi_{i}^{\text {best }}$
where $M_{i}^{\max }$ is the maximum induced motion; $M_{i}^{k}, M_{i}^{k-1}$ are the induced motion of the $i$ th krill at the $k$ th and $(k-1)$ th movement; $\omega_{n}$ is the inertia weight of the motion induced; $\alpha_{i}^{\text {new }}, \alpha_{i}^{\text {target }}$ are the local and the target effect, respectively; $F_{w}, F_{b}$ are the worst and the best position respectively, among all krill individuals, of the

population; $F_{i}, F_{j}$ are the fitness value of $i$ th and $j$ th individuals, respectively; $i$ is the current iteration number and $i_{\max }$ is the maximum iteration number.

To identify the neighboring members of each krill individual, a sensing distance $\left(S_{d_{i}}\right)$ parameter is used. If the distance between the two individual krill is less than the sensing distance, that particular krill is considered as neighbor of the other krill. The sensing distance may be defined by:

$$
\begin{equation*}
s d_{i}=\frac{1}{5 S} \sum_{j=1}^{s}\left|X_{i}-X_{j}\right| \tag{26}
\end{equation*}
$$

where $S$ is the number of krill individuals surrounding the particular krill; $X_{i}, X_{j}$ are the position of the $i$ th and $j$ th krill, respectively.

## Foraging action

The foraging motion $M_{f_{i}}^{k}$ is covered in terms of two main effective parameters. The first one is the current food location and the second one is the previous experience about the food location. This motion can be expressed for the $i$ th krill individual as follows:
$M_{f_{i}}^{k}=0.02 \beta_{i}+\omega_{x} M_{f_{i}}^{k-1}$

سفارش ترجمه اين مقاله

Fig. 5. Voltage deviation convergence graph using different algorithms of IEEE 118bus with UPFC.
$\beta_{i}=2\left(1-\frac{i}{i_{\max }}\right) F_{i} \frac{\sum_{j=1}^{s} \frac{x_{j}}{F_{j}}}{\sum_{j=1}^{N_{S}} \frac{1}{F_{j}}}+\Gamma_{i}^{\text {best }} \Psi_{i}^{\text {best }}$
where $\omega_{x}$ is the inertia weight of the foraging motion; $M_{f_{i}}^{k-1}, M_{f_{i}}^{k}$ is the foraging motion of the $i$ th krill at $(k-1)$ th and $k$ th movement.

## Random diffusion

The diffusion process of the krill individuals is considered as a random phenomenon. It may be represented in terms of a maximum diffusion speed and a random directional factor and may mathematically be expressed by:
$M_{d_{i}}^{k}=\lambda M_{d}^{\max }$
where $M_{d}^{\max }$ is the maximum diffusion motion; $\lambda$ is the directional vector uniformly distributed between ( $-1,1$ ).

## Position update

Finally, the position of the $i$ th krill during the time interval $t$ to $\Delta t$ may be expressed as:

Table 12
Simulation result of different algorithms for simultaneous minimization of loss and voltage deviation (IEEE 118-bus system without UPFC).

$x_{i}(t+\Delta t)=x_{i}(t)+\Delta t\left(M_{i}^{k}+M_{f_{i}}^{k}+M_{d_{i}}^{k}\right)$
where
$\Delta t=c_{p} \sum_{i=1}^{N}\left(u_{i}-l_{i}\right)$
where $N$ is the total number of control variables; $u_{i}, l_{i}$ are the upper and lower limits of the $i$ th control variable; $c_{p}$ is the position constant factor.

Moreover, to improve the behavior of the individual Krill, two adaptive genetic operators of DE are added to the proposed algorithm. These two operators are briefly described below:

## Genetic operators

To improve the performance of the algorithm, genetic reproduction mechanisms are incorporated into the algorithm. The introduced adaptive genetic reproduction mechanisms are crossover and mutation which are inspired from the classical DE algorithm. These two operations are described as follow:

## Crossover

In this process, depending on crossover probability, each krill individual interacts with others to update its position. The $j$ th components of the $i$ th krill may be updated by

$$
\Psi_{i, j}=\left\{\begin{array}{ll}
\Psi_{r, j} & \text { if rand }<c_{r}  \tag{32}\\
\Psi_{i, j} & \text { else }
\end{array} \quad \text { where } r=1,2,3 \ldots, i-1, i+1, \ldots, N_{P}\right.
$$

where $c_{r}=0.2 \Gamma_{i}^{\text {best }}$

## Mutation

The mutation operation creates mutant vectors $\Psi_{i, j}^{m}$ by perturbing the vector $\Psi_{\text {best }, j}$ with the difference of two other randomly selected vectors $\Psi_{o, j}$ and $\Psi_{p, j}$ as per following equation.
$\Psi_{i, j}^{m}=\Psi_{\text {best }, j}+\mu\left(\Psi_{o, j}-\Psi_{p, j}\right)$
The updated position of $\Psi_{i, j}^{\mathrm{mod}}$ is selected from $\Psi_{i, j}^{m}$ and $\Psi_{i, j}$ using mutation probability $\mu_{p}$ as follows:
$\Psi_{i, j}^{\bmod }= \begin{cases}\Psi_{i, j}^{m} & \text { if rand } \leqslant \mu_{p} \\ \Psi_{i, j} & \text { if rand }>\mu_{p}\end{cases}$

## Opposition based learning

Various optimization techniques start with some initial solutions and gradually try to improve them by converging them towards optimal values. Whenever any predefined criteria are satisfied, the search process stops. In the absence of any priori information, random guesses are made for taking up an initial solution. The distance of the random initial guesses from the optimal solution determines the computational time of execution of the search algorithm. Opposition-based learning (OBL) introduced by Tizhoosh [27] is one of the most successful concepts in computational intelligence, which enhances the search abilities of the conventional population based optimization techniques in solving nonlinear optimization problem. The main idea behind OBL is to consider the opposite of an assumption or a guess and comparing it with the original assumption, thereby improving the chances to find a solution faster. By simultaneously checking the opposite solution, the chance of starting with a closer or fitter solution can be improved. The OBL concept is based on the opposite point and opposite number which are defined as the following:

Opposite number: Let $x \in[\alpha, \beta]$ be a real number. Its opposite number $x^{0}$ is defined by:
$x^{0}=\alpha+\beta-x$
Opposite point: Let $P\left(x_{1}, x_{2}, \ldots, x_{T}\right)$ be a point in T-dimensional space, where $x_{r} \in\left[\alpha_{r}, \beta_{r}\right], \forall r \in\{1,2, \ldots, T\}$. The opposite point $P^{0}\left(x_{1}^{0}, x_{2}^{0}, \ldots, x_{T}^{0}\right)$ is defined by its components:
$\chi_{r}^{0}=\alpha_{r}+\beta_{r}-x_{r}$

## Opposition based optimization

Opposition based optimization is based on opposition-based initialization and opposition-based generation jumping which are briefly described below:

Opposition-based initialization. In absence of priori knowledge, the only choice to create an initial population is random number generation. Oppositional learning can be utilized to obtain a fitter starting candidate solution without any prior knowledge about the solutions.

Initialization of opposite population ( $O P$ ) may be described as follows:

```
for \(r=1: n_{p}\left(n_{p}=\right.\) population size \()\)
    for \(s=1: n_{d}\left(n_{d}=\right.\) number of control variables)
        \(O P_{r, s}=a_{s}+b_{s}-P_{r, s}\)
    end
end
```

Opposition-based generation jumping. A similar approach can be applied to the current population by which the evolutionary process can be forced to jump to a new solution candidate, which may be more fit than the current one. After generating a new population by using KHA, the opposite population is generated based on a jumping rate $j_{r}$.

Opposite population jumping based on jumping rate as described below:

```
if rand \((0,1)<j_{r}\left(j_{r}=\right.\) jumping rate \()\)
    for \(r=1: n_{p}\left(n_{p}=\right.\) population size \()\)
        for \(s=1: n_{d}\left(n_{d}=\right.\) no of control variables)
            \(O P_{r, s}=a_{s}+b_{s}-P_{r, s}\)
        end
    end
end
```

## Oppositional krill herd algorithm applied to ORPD problem

The procedure for implementing the OKHA algorithm in solving ORPD problem for minimization of active power loss and voltage deviations can be summarized as follows:

Step 1: Initialize all independent variables such as all generators' voltages, tap settings of regulating transformers, reactive power injections, the active and reactive power injected by UPFC devices, voltage of UPFC connected bus are randomly within their specified operating limits.
Step 2: Update the independent variables of each initial solution string using the following expression to generate oppositional population.

$$
O P_{r, s}=a_{s}+b_{s}-P_{r s}
$$

where $r=1,2, \ldots, n_{p} ; s=1,2, \ldots, n_{d} ; P_{r, s}$ is the $s$ th independent variables of the $r$ th vector of the population; $O P_{r, s}$ is the $s$ th independent variables of the $r$ th vector of the opposite population; $n_{p}$ is the population size and $n_{d}$ is the number of independent variables.
Step 3: Run the Newton-Raphson load flow analysis to determine the dependent variables such as 'slack bus power, load voltages, power flow through the transmission line, source voltages of series and shunt branches of the UPFC devices and check whether they satisfy the operating limits or not. If any of these parameters violate the operating limits; discard that population set and re-initialize the corresponding set. Depending upon the population size, several solutions are generated. Each feasible solution set represents the initial position of each krill individual.
Step 4: Evaluate the fitness values of the current population ( P ) and oppositional population (OP) sets.
Step 5: Select $n_{p}$ number of fittest individuals from $\{P \cup O P\}$.

Step 6: Sort the solutions from best to worst.
Step 7: Select few best solutions for elitism.
Step 8: Evaluate the three motion index, namely, motion induced by other individual; foraging motion and random diffusion.
Step 9: Modify the non-elite krill individuals' position.
Step 10: Apply crossover and mutation to update the position of each non-elite krill individuals. The updated position of krill individual represents the different independent variables. The parameters which are optimized in the OKHA algorithm.
Step 11: Check whether the independent variables violate the operating limits or not. If any independent variable is less than the minimum level it is made equal to minimum value and if it is greater than the maximum level it is made equal to maximum level.
Step 12: Run Newton-Raphson load flow analysis to determine the dependent variables and check whether they satisfy the system operating constraints or not. Replace the infeasible solutions by the best feasible solutions.
Step 13: Evaluate the opposite population of the current population and calculate the fitness values of the opposite population based on a jumping rate $j_{r}$ (i.e. jumping probability).
Step 14: Select $n_{p}$ fittest individuals from the union of the current population and the opposite population.
Step 15: Go to Step 4 for the next iteration until termination criterion is reached.
Step 16: Finally, the optimal parameters such as generators' voltages, tap settings of regulating transformers, reactive power injections, the active and reactive power injected by UPFC devices, voltage of UPFC connected bus and the location of the UPFC incorporated bus that optimized by the OKHA algorithm are identified.

## Simulation results and discussions

To check the feasibility of the proposed OKHA method it is tested on IEEE 57-bus and IEEE 118 -bus test systems and to validate the performance of the proposed method, it is compared with DE, BBO and conventional KHA approaches. The program is written in MATLAB-7 software and executed on a 2.5 GHz core i3 processor with 4-GB RAM. For implementing the DE, BBO, KHA and OKHA population size of 50 and the maximum number of generation (iterations) of 100 are taken in the simulation study. Since the performance of any algorithm depends on its input parameters, they should be carefully chosen. After several runs, the following input parameters shown in Table 1 are found to be the best for the optimal performance of the DE, BBO, KHA and OKHA algorithms.

## Test system 1

Test system 1 represent IEEE 57-bus system [28] which consists of 80 branches, 7 generator buses and 15 branches under load tap setting transformer. The possible reactive power compensation buses are 18,25 and 53 . The base load of the system is 1272 MW and 298 MVAR. The upper and lower voltage limits at all the buses are taken as 1.10 p.u. and 0.95 p.u., respectively. The tap setting limits of all the regulating transformer are set to 0.9 p.u. for lower bound and to 1.1 p.u. for upper bound. In order to analyze the system under stressed condition, active and reactive power demand of each load bus are multiplied by 1.25 . The line flow limits of all the lines are taken as two times of the base case line-flows. The lower and upper limits of the series voltage sources of the UPFC are taken within the interval of $0-0.2$ p.u., respectively, and the limiting
values of the shunt voltage sources of the UPFC are taken in between 0 and 1.1 p.u. The phase angles of these sources are within the range of $0-2 \pi$. The shunt and series impedances of installed UPFC are taken as $(0.01+j 0.1)$ p.u. and $(0.001+j 0.2)$ p.u., respectively.

## Single objective function

Case I: Loss minimization. The IEEE 57 bus system is first considered without the allocation of any UPFC device within it. The optimal values of the control variables including power loss and voltage deviation evaluated using the BBO, DE, KHA and OKHA technique are listed in Table 2. It can be seen that the proposed OKHA technique gives the best loss among all the techniques without violating any operating constraint limits. Furthermore, BBO, DE, KHA and OKHA approaches are applied to UPFC based ORPD problem to find the optimal rating and location of UPFC for minimizing the real power losses and the corresponding results are illustrated in Table 3. It is observed from the simulation results that the loss obtained by BBO, DE, KHA and OKHA method are 40.5535 MW, 41.3003 MW, 40.2431 MW and 39.8134 MW respectively for without UPFC. However, after incorporating the UPFC in optimal position, loss obtained by BBO ( 39.3640 MW), DE ( 40.7651 MW), KHA (39.3642 MW) and OKHA (38.4255 MW) methods are substantially reduced. It is also observed from Tables 2 and 3 that the proposed OKHA method gives much better transmission loss than BBO, DE and KHA algorithms for both the cases. The convergence graph of BBO, DE, KHA and OKHA for transmission loss objective in IEEE 57 bus system without UPFC is given in Fig. 2.

Case II: voltage deviation minimization. In order to further evaluate the performance of the proposed OKHA optimization technique, normal ORPD and UPFC based ORPD for voltage deviation minimization objective are investigated. The results obtained for this objective function by BBO, DE, KHA and OKHA are reported in Tables 4 and 5 , respectively without and with UPFC. In this case, the sum of voltage deviations obtained by BBO, DE, KHA and OKHA methods are 1.0409 p.u., 1.1104 p.u., 1.0182 p.u. and 0.9954 p.u., respectively, without UPFC. As seen in Table 4, the sum of voltage deviations in this case has been greatly reduced in all load buses using OKHA compared to BBO, DE and KHA algorithms. The UPFC device is then optimally placed on IEEE 57 bus system using the discussed techniques to reduced the voltage deviation further. The voltage deviation minimizations obtained by BBO, DE, KHA and OKHA methods are 0.9743 p.u., 1.0249 p.u., 0.9278 p.u. and 0.8942 p.u., respectively. It clearly suggests that the OKHA technique produces better voltage deviation results as compared to other techniques. The voltage deviation convergence graph using different algorithms on the IEEE 57 bus with UPFC is shown in Fig. 3.

## Multi-objective function

To assess the efficiency of the proposed algorithm, multiobjective problem which minimizes the transmission loss and voltage deviation simultaneously is carried out. The objectives of transmission loss and voltage deviation are typically noncommensurable and conflict with each other in this multiobjective optimization problem. It is generally impossible to identify a solution while simultaneously optimizing the objectives. Table 6 shows the optimal setting of control variables, loss and voltage deviation for IEEE 57-bus test system obtained using the various methods without incorporating any facts devices. It can be easily concluded from the simulation results that the proposed method has resulted with better best compromise solution for both transmission loss and voltage deviation. To reduce the transmission loss and voltage deviation further, a UPFC device is then optimally placed on the same test system using the discussed
techniques. A comparison is made among the best compromise solution obtained from the proposed OKHA method and the solutions obtained by BBO, DE and KHA algorithms. The results of this comparison are shown in Table 7. As it is shown in Table 7, the results achieve from the presented OKHA method for the best transmission loss and voltage deviation are significantly reduced to those of the BBO, DE and KHA algorithms which demonstrates the reliability of the OKHA algorithm.

## Test system 2

In order to further demonstrate the effectiveness and validate the feasibility of the proposed OKHA algorithm, simulations are carried out for ORPD problem in the IEEE 118-bus test system [29]. The network consists of 186 branches, 54 generator buses and 12 capacitor banks. Nine branches $8-5,26-25,30-17,38-37$, $63-59,64-61,65-66,68-69$, and $81-80$ are tap changing transformers. The total real and reactive power demands for base case are 3668 MW and 1438 Mvar, respectively. However, to analyze performance of various techniques under stressed condition, active and reactive power demand of each load bus are increased by $25 \%$. In this study, the limiting tap setting values for tap changers are between 0.9 and 1.1 p.u., the allowed voltage changes are between 0.95 and 1.1. The voltage limits of the series sources of the UPFC are taken as $0-0.2$ p.u. and the lower and upper limits of the shunt voltage sources of the UPFC are 0 p.u. and 1.1 p.u., respectively. The phase angles of both series and shunt sources are within the range of $0-2 \pi$. The shunt and series impedances of installed UPFC are taken as $(0.01+j 0.1)$ p.u. and $(0.001+j 0.2)$ p.u., respectively.

## Single objective function

Case I: Loss minimization. The IEEE 118 bus system is first considered without the allocation of any UPFC device within it. The optimal values of the control variables including power loss and voltage deviation are evaluated using the OKHA technique and then compared against the values obtained using BBO, DE and KHA techniques. It can be seen from Table 8 that the active power losses achieved by the BBO, DE, KHA and OKHA algorithm without UPFC are equal to 188.9462 MW, 194.9291 MW, 183.5578 MW and 179.3371 MW, respectively which clearly suggests that the proposed OKHA technique gives the best loss among all the discussed techniques. Afterward, to judge the algorithms' performance under complicated environment, the UPFC device is incorporated in the same test system. The optimal results of the various methods are presented in Table 9. It can be observed in Table 9 that the optimal location of the UPFC device for improved secure results for loss minimization for BBO, DE, KHA and OKHA techniques are 100106, 103-110, 108-109 and 103-105 respectively. It can also be observed that all the methods are able to reduce the transmission loss effectively by placing the UPFC in optimal positions. Moreover, the result in Table 9 shows that the proposed OKHA optimization method outperforms other optimization techniques in terms solution quality and computational time. The transmission loss convergence graph using different algorithms on the IEEE 118 bus with UPFC are shown in Fig. 4.

Case II: Voltage deviation minimization. The optimal solutions obtained by BBO, DE, KHA and OKHA for the objective of voltage profile improvement of IEEE 118 bus system of normal ORPD and UPFC based ORPD are given in Tables 10 and 11, respectively. It may be noted that all the control variables are in their specified limits. It is observed from the simulation results of Table 10 that even without incorporating UPFC the voltage deviations are substantially been reduced from 1.7533 p.u. to 1.0250 p.u. by BBO, 1.4466 p.u. to 1.1104 p.u. by DE, 2.0423 p.u. to 0.8588 p.u. by KHA and 2.4609 p.u. to 0.7740 p.u. by OKHA as compared to the
previous case. However, it is also found that the reduction of voltage deviation is most significant for OKHA among all the algorithms. Moreover, from Table 11 is found after incorporating UPFC in optimal location the voltage deviation is improved from 1.0250 p.u to 1.0124 p.u. using BBO, 1.1104 p.u. to 1.0312 p.u. using DE, 0.8588 p.u. to 0.7318 p.u. using KHA, and 0.7740 p.u. to 0.6742 p.u. using OKHA. Therefore, it can be concluded that by installing proper size of UPFC at proper place, the voltage profile of the power system can significantly be improved. Moreover, it is observed that voltage profile improvement ability of OKHA is best among all the discussed algorithms. The voltage deviation convergence graph using different algorithms using UPFC is shown in Fig. 5.

## Multi objective function

In order to validate the effectiveness of the proposed procedure for multi-objective problem, it is applied on IEEE 118-bus system to minimize the transmission loss and voltage deviation simultaneously. To validate the superiority, the proposed OKHA method is compared with the BBO, DE and KHA algorithms. The optimal control variable settings, transmission loss and voltage deviation obtained using various intelligent techniques are given in Table 12. It can be seen from Table 12 that the proposed OKHA technique gives the best compromising solutions among all the techniques without violating any operating constraint limits. Moreover, for minimizing the real power losses and voltage deviation further, a UPFC device is optimally placed on IEEE 118 -bus system by the presented approaches. Results obtained by the proposed OKHA method are compared with KHA, BBO and DE methods which are summarized in Table 13. The simulation results clearly show that the best compromising transmission loss and voltage deviation obtained by the proposed OKHA approach is least compared with other methods which emphasizes its better solution quality.

## Conclusion

ORPD is an important problem in power engineering which has discrete variables, nonlinear objective function, and nonlinear constraints. In this paper, ORPD is solved using BBO, DE, KHA and OKHA algorithms to minimize the voltage deviation and total transmission loss. Moreover, to reduce the voltage deviation and transmission loss further, UPFC devices are optimally placed using the same algorithms. The performance of the proposed algorithms are demonstrated through their evaluation on the IEEE 57-bus and IEEE 118-bus power systems. The simulation results show that OKHA has better searching ability to find optimal solution as compared to other algorithms. So, it is believed that the proposed OKHA approach is capable of efficiently and effectively solving reactive power dispatch problem and will become a promising candidate for the optimal UPFC allocation problem problems. Also it may be observed from simulation results that computational time of OKHA in all test cases is lesser than that of conventional KHA, BBO and DE. Considering all these results of the study it can be concluded that OKHA performs better, than other methods in terms of solution quality, convergence speed and computational time.
